

CASES OF HYPOVITAMINOSIS ON THE BACKGROUND OF HELMINTHIASIS

Aslonova Marjona Ramazonovna

Bukhara State Medical Institute named after Abu Ali ibn Sino

Summary

Reducing parasitic diseases is one of the pressing issues. To overcome this problem requires the study of metabolic processes between the host and the parasite. Studies have shown that the accumulation of certain vitamins in the body of helminths depends on the concentration of vitamins absorbed in the digestive system of the host. Through the interaction between the host and the parasite, the helminths absorb the vitamins that are absorbed in the gut and intestines. Our research was based on the study of vitamins in parasitic tissues. Research in this area dates back to the forty-eighth century. They have done very little research in this area. We have used calorimetry, spectrophotometry, fluorometric methods and laboratory methods in our presentations.

Резюме: Уменьшение паразитарных заболеваний является одной из актуальных проблем. Для преодоления этой проблемы необходимо изучение метаболических процессов между хозяином и паразитом. Исследования

показали, что накопление определенных витаминов в организме гельминтов зависит от концентрации витаминов, всасываемых в пищеварительной системе хозяина. Благодаря взаимодействию между хозяином и паразитом гельминты поглощают витамины, которые всасываются в кишечнике и кишечнике. Наши исследования были основаны на изучении витаминов в тканях паразитов, исследования в этой области восходят к сорок восьмому веку. Они провели очень мало исследований в этой области: в наших презентациях мы использовали калориметрию, спектрофотометрию, флуорометрические методы и лабораторные методы.

Ключевые слова: гельминты. больные гельминтозами. витамины С. В₁. В₁₂. А. Е.

Introduction

Data from parasitological studies of environmental objects made it possible to determine that the main routes of infestation of invasive material as a result of violations of the requirements for the design and equipment, maintenance and operation of water intake facilities are storm ($37.2 \pm 0.5\%$) and flood ($40.3 \pm 0, 3\%$) of water, as well as the use of individual buckets ($22.5 \pm 0.1\%$). [3] Drinking water from a non-centralized water supply is parasitologically unsafe, it contains lamblia cysts, cryptosporidium oocysts, tenciida oncospheres, roundworm eggs, toxocar, pinworms, whipworms. Measures for the protection of non-centralized water supply structures from the receipt of invasive material should include: technical arrangement of structures, creation of sanitary protection zones, cleaning of bottom sediments, elimination of pollution sources.

Changes in social production and living conditions of the population of the Republic of Uzbekistan (development of private property, farming and individual production, the increasing trend of migration not only within the country but also in countries near and far abroad, the intensification of the processes of human transformation of nature, increased frequency of natural disasters) have changed the living environment of pathogens of intestinal parasitosis in the environment that strongly requires the adjustment and improvement of existing and development of new approaches to their prevention [1-28].

According to the world Bank, the economic damage caused by intestinal parasitosis ranks fourth among the losses caused by all diseases and injuries [5-22]. The world health organization has called on countries that register ascariasis to reduce the level of infection in the population by 80% by 2010.

Purpose

The aim of the study was to find out the peculiarities of vitamin C metabolism. B₁, B₁₂, E, A in trematodes (*Fasciola hepatica*, *Opistorchis felinus*), cestodes (*Taenia solium*, *Taeniarrhynchus saginatus*, *Hymenolepis nana*, *Diphyllobothrium latum*), nematodes (*Ascaris lumbricoides*, *Ascaris suum*, *Toxocara canis*, *Trichocephalus trichiurus*, *Trichinella spiralis*) and in patients with the development of a parasitic disease. Materials for analysis were collected parasites in meat processing plants [9-30], during expeditions to the centers of opisthorchiasis, when conducting experimental studies to gimenolepidoz and trichinosis, as well as patients with helminthiasis, who had their blood serum taken at the time of admission to the Bukhara region infectious diseases hospital. Installed, that in the tissues of trematodes cestodes and nematodes found vitamins C, B₁, B₁₂, E, A.[15] which helminths get from the intestinal contents or tissues of the host. In patients with helminthiasis, caused by flukes, cestodes and nematodes, it is characterized by a decrease in the levels of vitamins C, B₁, B₁₂, a, E in the blood serum [3-13].

The solution of questions of the formation of the host parasite system requires the study of metabolic processes, occurring as in the body of helminths, so in their masters. To understand the characteristics of the relationship, developing in the host parasite system. It is of interest to study the metabolism of vitamins in helminths and elucidate their role in the life of invasive organisms.[17] The studies carried out in this direction belong to the forties and eighties of the last century. They are not numerous, carried out using calorimetric, spectrophotometric, fluorometric methods, the results of which are often controversial [7-19].

Dedicated to the simultaneous study of the content of vitamins C, B₁, AT 12, E.A. in helminths and their metabolism in invasive organisms, the aim of the study was to elucidate the characteristics of the exchange of these vitamins in trematodes (hepatic and cat flukes).[9,11,15] cestode (unarmed, armed and dwarf tapeworms, wide tape) and nematodes (human roundworm, pork and dog; whipworm; trichinella) and in patients with the development of parasitic disease.

METHODS

Materials for analysis were collected parasites in meat processing plants, during expeditions to the foci of opisthorchiasis. When conducting experimental studies on hymenolepidosis and trichinosis, as well as patients with helminthiasis from whom blood serum was taken at the time of admission to the Bukhara regional infectious diseases hospital [4-25].

Vitamin C was determined by the dinitrophenylhydrazine method [12-20]. B1 vitamins. E. A - by the fluoremetric method [2-30]. The research results were processed statistically and presented in tables.

RESULTS AND DISCUSSION

An analysis of the data allows us to state. that in whole parasites and their tissues significant quantities of both water-soluble (C. B1. B12) and fat-soluble (E. A) vitamins are determined. In parallel with these results, significant changes are noted in the metabolism of these vitamins in the body of patients with helminth infections. When comparing the levels of vitamins in the blood serum of donors and patients with invasive diseases, it can be stated. that the levels of all the studied serum vitamins were significantly lower than the control values[13-19].

The fact is generally recognized. that ascorbic acid is actively involved in the redox reactions of the body. It. as known. serves as a hydrogen donor. Ascorbic acid is an important biological substance. actively participating in all metabolic reactions of the body[16-27]. Vitamin C (ascorbic acid) is present in significant quantities in whole helminths (fasciol. Opisthorchis; human roundworm. Pork and dog; whipworm) and in their tissues (intestines. Ovaries. Testes. Pork roundworm muscles). as well as in the larvae of tissue nematodes (trichinella). However, in cestodes (bovine and pork tapeworms. Dwarf tapeworm. Wide ribbon), vitamin C levels were significantly lower. than in trematodes and nematodes (Table 1).

Table 1 The content of vitamins in helminths and their tissues ($\mu\text{mol} / \text{kg}$ of raw tissue)

№ p/p	Vitamins		n	C	B1	B12	E	A
	Helminths							
Trematodes								
1	Fasciola hepatica		7	346±17	0,18±0,004	3,04±0,05	24,8±0,56	0,021±0,003
2	Opisthorchis felineus		12	290±12	0,19±0,003	3,12±0,04	23,4±0,45	0,022±0,004
Cestodes								
3	Taeniarhynchus sa- ginatus		5	24,8±1,2	0,17±0,004	15,04±0,07	20,3±0,32	0,017±0,003
4	Taenia solium		5	28,6±1,3	0,18±0,002	12,04±0,06	25,4±0,34	0,018±0,003
5	Hymenolepis nana		15	18,1±0,9	0,20±0,002	9,08±0,07	20,4±0,41	0,019±0,004
6	Diphyllobothrium latum		5	18,9±0,9	0,17±0,003	24,07±0,12	22,2±0,42	0,018±0,003
Nematodes								
7	Ascaris lumbricoides		5	478±18	0,14±0,003	8,12±0,05	34,2±0,44	0,013±0,002
8	Ascaris suum:		10	494±11	0,12±0,004	8,22±0,06	36,2±0,38	0,012±0,002
	- intestines		10	749±17	0,15±0,004			0,037±0,003
	- ovaries		10	494±12	0,13±0,003			0,017±0,003
	- testes		10	488±13	0,13±0,003			0,018±0,004
	- muscles		10	290±8	0,09±0,002			0,021±0,005
9	Trichocephalus tri- chiurus		10	449±11	0,15±0,003	7,34±0,12	30,1±0,92	0,018±0,003
10	Toxocara canis		7	483±9	0,13±0,004	7,98±0,09	32,4±0,28	0,019±0,003
11	Trichinella spiralis(larvae)		10	505±17	0,14±0,004	7,68±0,08	35,2±0,43	0,020±0,004

Low levels of vitamin C in cestodes are associated with the ability of the latter to synthesize ascorbic acid [5,6]. and the decrease in vitamin C reserves in hosts invaded by helminths is due not so much to its consumption. how much with the expenditure on the protective and adaptive mechanisms of the patient [16-28].

Helminths. containing significantly higher levels of vitamin C. in their tissues than those found in the tissues of their hosts. able to absorb vitamin C from the intestinal contents and tissues of the patient. This thesis is confirmed by the presence of maximum values of vitamin C in the intestines of the helminth and various concentrations of vitamin in the tissues of pork roundworms. collected in the months of August-October and February-March. Ascaris intestines are the first to come into contact with swallowed food [14-26].. which should determine the higher vitamin content in it. About. that vitamin C is not synthesized in the parasite. but absorbed from the host. It is confirmed by the dependence of the vitamin content in the helminth on the nutritional characteristics of its hosts.

CONCLUSION

According to the World Health Organization, vitamin B deficiency is a serious problem for public health. Vitamin B is an important factor that plays a direct role in the process of differentiation and maturation of lung tissue. In addition, other vitamins are very important for the body. Assimilation of these vitamins by parasitic helminths showed that they accumulate in the tissues when we determined by the results of the study[4-17].

It has been established that the tissues of trematodes of cestodes and nematodes contain a significant amount of vitamins C. B1. AT 12. A. E. Helminths receive vitamins due to the predominant absorption of the latter from the intestinal contents and tissues of the host [7-18].
